

AI Capstone Project – Idea Proposal Template

(Student Submission)

This is a template proposal for your graduation project idea that should be delivered to get approval

1. Project Title

Provide a **clear and descriptive name** that accurately represents the project's main features, **in addition to a short, catchy title** suitable for marketing and presentation purposes.

2. Project Idea (problem you're solving?)

Clearly describe the real-world problem your project addresses:

- What is the problem happening?
- Who experiences it (what section of people or industry segment)?
- Why is it worth solving (benefits and cost reduction if we apply it)?

Important notes:

- Solutions to the problem you choose **may already exist**, and that is okay.
- Your project can improve an existing solution by:
 - Better user experience
 - Smarter or more practical use of AI
 - Automation of manual or repetitive work
 - Cost reduction of AI tools used
- Avoid ideas that are “cool” or complex but **do not solve a real need**.
- Think of this as something that *could* be a **startup MVP**, not just a technical experiment.

Rules:

The problem should be observable, repeatable, or measurable in real life (the problem must be real and specific), avoid vague or generic problems.

3. Users

Describe the **main users** of your system (**Primary users vs Secondary users**):

- Who will use this application?
 - Are they technical or non-technical?
 - Geographic focus (e.g., Egypt, MENA region, global)
 - Language support (English / Arabic / Both)
-

4. Proposed Solution (High-level)

Explain **what you will build** to solve your problem without delving into technical details.

- What kind of application is this? (Web app, assistant, chatbot, tool, platform)
- What does the user interact with?
- What is the main flow from user input to system output?

Do NOT list features yet. Focus on the General solution idea

5. Role of AI

This section is critical.

You should answer in your proposal **all** of the following clearly:

5.1 Why is AI needed here?

- What part of the problem **cannot be solved well without AI**?
- Why is a normal rule-based or CRUD application not enough?

5.2 What will the AI actually do?

Select and describe clearly (not technical details) the AI Features in your application (General Flow)

Avoid vague statements

6. Project Scope (Boundaries)

prevents over-scoping.

6.1 What the project **WILL** do

List the **core capabilities of your application only**.

Note: This section is mandatory and will be used during evaluation.

6.2 What the project will **NOT** do

Explicitly list things you are **not building**.

If it's not listed here, it's considered **out of scope**.

7. Data (What information does your system need to function?)

You need to describe the **type of content**, the **data you need**, and the **data you will store** (do not talk about technical things, and do not discuss how it is processed), **Synthetic or publicly available data may be used if real data is not accessible.**

Rules:

- Data must be clearly identifiable
-

8. Team Responsibilities

Briefly assign **the main responsibility scope of each sub-team** in your team

Example:

Area	Members
AI (Model & Intelligence) Responsible for defining AI behavior, selecting models, and validating AI outputs.	
Backend & AI Integration Responsible for APIs, business logic, and integrating AI services into the system.	
Frontend & User Interface – User flows, UI design, and frontend implementation	
Mobile (if applicable) – Mobile-specific UI and integration	
Testing & QA – Functional testing, edge cases, and validation	

Notes:

- You can add other sections if needed
 - All team members work together; responsibilities are shared.
 - Make sure everyone understands the project and has enough information to contribute.
-

Proposal Summary / Final Notes

- Keep your proposal clear and concise (**1–2 pages max**).
- Focus on the **real problem, target users, and high-level solution**.
- Clearly describe **the role of AI** without technical implementation details.
- Define **project scope**: what it will and will not do.
- Avoid buzzwords, vague statements, or over-engineering.
- Ensure the solution could realistically be a **minimum viable product (MVP)**, not just a technical experiment.
- Make sure the proposal is **ready for review** and understandable without additional explanation.
